KEYLESS ENTRY SYSTEM USING AN MC146805F2()18-BIT MICROCOMPUTER UNIT

Prepared by
Michael Gallup and Vernon Goler
Microprocessor System Design
Austin, Texas

INTRODUCTION

The MC146805F2()1 is a single-chip microcomputer unit (MCU) containing 64 bytes of user RAM, 1089 bytes of user ROM, 191 bytes of self-check ROM, 16 bidirectional I/O lines, four input-only lines, two timer registers, and an on-chip oscillator. The MC146805F2()1 contains three distinct program modules, including:

- 1. Monitor
- 2. Demonstration Program (Keyless Entry System)
- 3. Self-Check Program (Self Test)

The self-check feature is fully described in the MC146805F2 data sheet and it can be used to verify operation of the MCU. The self-check routine is included in all MC146805F2 devices.

The monitor routine which is contained in all MC146805F2() 1 MCUs is not discussed as part of this application note. The monitor routine allows the user to evaluate the MCU using a standard RS-232 terminal. A copy of the keyless entry demonstration program listing is shown in Figure 2.

KEYLESS ENTRY SYSTEM

NOTICE

The keyless entry system using the MC146805F2() 1 8-bit microcomputer unit is not intended to be used by itself in a secure entry system. It is intended to be used only as an aid in better understanding the MC146805F2 MCU and how it can fit into a secure entry system.

The keyless entry system (referred to as a digital lock) is a dedicated MC146805F2()1 MCU, executing a program, that can control a larger configuration to form a security entry system. Figure 1 contains a schematic diagram of the digital lock complete with keypad and liquid crystal display.

The function of the digital lock is to accept inputs from a 3×4 keypad and, if the inputs are in the correctly coded sequence, generate an output which indicates the lock is open. However, if the input code sequence is not entered correctly, the digital lock MCU provides an alarm indication (logic 1) on pin 20 (PB2).

The user interfaces with the digital lock MCU through a 3×4 keypad and a wake-up push button. This allows multiple users to gain access to a secure area without the necessity of carrying a key. The LCD displays a dash for each keypad entry. This ensures that the user knows how many of the required keypad entries have been made.

The digital lock MCU has a feature which protects against trial-and-error attempts to gain entry. If two incorrect code combinations are entered, an alarm output is generated (PB2 goes high). The alarm condition remains active until the combination is entered or power is disconnected.

Once the correct combination has been entered via the keypad, the LCD spells out the word OPEN. From this time, the user has eight seconds to open the door or other locked device.

INITIALIZATION

When power is initially applied or if power is lost and then reapplied, the 8-digit combination code is lost in RAM. It now becomes necessary to enter a new 8-digit combination. This can be done by performing the procedure outlined in the Changing The Combination paragraph.

OPERATION

Two operating modes are described below. One is the normal user procedure to open the lock and the other describes a method to change the combination.

Opening The Lock

To open the lock:

 Press the wake-up push button and check that the LCD is clear.

- 2. Use the keypad to enter the 8-digit combination code. Note that each time a keypad switch is depressed a dash will appear on the LCD to indicate that a digit is entered. The total number of digits entered is equal to the total number of dashes.
- 3. Once the correct 8-digit combination code is entered, the LCD will display the word OPEN. The open signal is then actived for approximately eight seconds. If the user fails to mechanically open the door (or other entry device) during the 8-second time period, the above procedure should be repeated to again gain entry.

NOTE

If an incorrect code is entered for the second time, the alarm signal becomes active. The alarm will stay active until the correct code is entered as described above or until power is removed.

Changing The Combination

To change the combination:

 Press the wake-up push button and check that the LCD is clear.

- Use the keypad to enter the 8-digit change combination code number 14680502. Note that each time a keypad switch is depressed, a dash will appear on the LCD to indicate that a digit is entered. Once all eight digits are entered the LCD goes blank.
- Use the keypad to enter the new 8-digit combination code. As before, a dash appears each time a keypad switch is depressed.
- 4. Once the eight new digits are entered, the word VERIFY appears on the LCD. This is a prompt for the user to enter the same 8-digit combination code as in 3 above. If the second 8-digit entry is not exactly the same as the first, the word ERROR is displayed on the LCD. In this case, the user must repeat the procedure from 3 above.

NOTE

Changing the combination does not open the lock. Once the new code has been verified, the LCD goes blank. The lock can then be opened as described in the Opening the Lock paragraph.
